

Association of British Clinical Diabetologists (ABCD) and Diabetes UK joint position statement and recommendations for non-diabetes specialists on the use of sodium glucose co-transporter 2 inhibitors in people with type 2 diabetes (January 2021)

Authors: Umesh Dashora,^A Robert Gregory,^B Peter Winocour,^C Ketan Dhatariya,^D Susannah Rowles,^E Andrew Macklin,^F Gerry Rayman,^G Dinesh Nagi,^H Katie Whitehead,^I Hannah Beba,^J Parijat De^K and Dipesh C Patel;^L on behalf of the ABCD executive committee and Diabetes UK

ABSTRACT

Sodium glucose co-transporter 2 (SGLT2) inhibitors are now an established class of medications for the treatment of type 2 diabetes (T2D), no longer reserved for use by specialists in diabetes. They are being used increasingly for their cardiac and renal benefits by primary care, cardiology and renal teams for indications in parallel with diabetes care as part of holistic management. This guidance provides essential information on SGLT therapy, including the main advantages and the important risks of which healthcare professionals should be aware.

KEYWORDS: SGLT2 inhibitors, type 2 diabetes, non-diabetes specialists, ABCD, Diabetes UK

DOI: 10.7861/clinmed.2021-0045

What is new?

The American Diabetes Association / European Association for the Study of Diabetes (ADA/EASD) consensus report 2019 update recommends the use of sodium glucose co-transporter 2 (SGLT2) inhibitors with proven cardiovascular and renal benefits as a second-line therapy independent of glycosylated haemoglobin (HbA1c) target after metformin when there is a need to address atherosclerotic cardiovascular disease (previous myocardial infarction, angina or peripheral vascular disease), heart failure, renal impairment, excess body weight or risk of hypoglycaemia.¹

SGLT2 inhibitors are being increasingly used in primary care and by non-diabetes specialist teams.

SGLT2 inhibitors are commonly associated with genital mycotic infections. They are also associated with a small increase in risk of diabetic ketoacidosis in people with type 2 diabetes (T2D).

Here, we summarise available evidence and provides guidance on how to reduce adverse effects of SGLT2 therapy and manage them when they occur.

What are the types of diabetes?

Type 1 diabetes (T1D) is caused by the destruction of the insulin producing beta cells in the pancreas.² People with this type of diabetes rapidly become dependent on insulin for survival. Insulin supplementation should never be stopped even for a short period in absolute insulin deficiency as this risks diabetic ketoacidosis (DKA).

T2D develops because of a mix of resistance to insulin action and deficiency of insulin secretion with variable genetic susceptibility combined with environmental factors (like sedentary lifestyle or obesity). Pharmacotherapy is often required if diet and exercise

Authors: ^Aconsultant (diabetes), honorary reader, deputy sub-dean and meeting secretary ABCD, Conquest Hospital, St Leonards-on-Sea, UK; ^Bconsultant physician, University Hospitals of Leicester NHS Trust, Leicester, UK; ^Cconsultant physician and clinical director, East and North Hertfordshire NHS Trust, Stevenage, UK; ^Dconsultant physician and honorary professor, Norfolk and Norwich University Hospitals NHS Foundation Trust, Norwich, UK; ^Econsultant diabetologist, Pennine Acute Hospitals NHS Trust, Manchester, UK; ^Fconsultant diabetologist, Dorset County Hospital NHS Foundation Trust, Dorchester, UK; ^Gconsultant diabetologist, honorary professor and clinical lead for diabetes GIRFT, East Suffolk and North East Essex NHS Foundation Trust, Ipswich, UK; ^Hhonorary consultant in diabetes and endocrinology, and Ex Officio (Chair) ABCD, Pinderfields Hospital, Wakefield, UK; ^Ipractice nurse, The Hollies Medical Centre, Sheffield, UK; ^Jsenior clinical pharmacist in diabetes and endocrinology, and co-chair diabetes and endocrinology committee UKCPA, County Durham and Darlington NHS Foundation Trust, Durham, UK; ^Kconsultant physician in diabetes and endocrinology, Sandwell and West Birmingham Hospital NHS Trust, Sandwell, UK; ^Lconsultant physician in diabetes and endocrinology, and honorary associate professor, University College London, London, UK

alone are not sufficient to control diabetes. Metformin is the first-line therapy. SGLT2 inhibitors or glucagon-like peptide 1 (GLP-1) analogues with proven cardiovascular benefit are increasingly being used as a second-line therapy based on recent clinical trial results. As diabetes progresses, combination therapy may be needed and insulin may be required to manage hyperglycaemia. Some people with apparent T2D may actually have a slowly progressing T1D (latent autoimmune diabetes in adults (LADA) with positive insulin auto-antibodies) or damage to their entire pancreas (type 3c diabetes). These people are at higher risk of DKA. Other groups with T2D are also ketosis-prone for unknown reasons.³ T2D may present with DKA in some people (particularly of Black ethnicity) but these people often do not require insulin in the long term. In addition, people with T2D and severe illness can have an increase in insulin requirement that precipitates DKA.

How is diabetes diagnosed?

Diabetes is diagnosed by a single fasting plasma glucose ≥ 7 mmol/L or an HbA1c ≥ 48 mmol/L in the presence of osmotic symptoms (polydipsia, polyuria, tiredness or thirst) or the same levels on two different occasions in the absence of symptoms.² Up to 90% of people with T1D have positive auto-antibodies at presentation. Serum or urine C-peptide is initially low, but present. This declines with time, such that C-peptide becomes undetectable in most by 5 years. C-peptide production also decreases in T2D, although much more slowly.

The unmet need in the treatment of people with T2D

Up to 50% of people with T2D die from cardiovascular disease with the increased mortality strongly attributed to diabetic kidney disease.^{4,5} Therefore, drugs with robust evidence of reducing cardiovascular and renal morbidity and mortality in people with T2D need to be used widely. Additionally, a number of treatment options for T2D are associated with unwanted side effects (such as hypoglycaemia and weight gain). Efficacious drugs not associated with such side effects are also highly desirable.⁶

Fig 1. Cardiovascular and renal effects of sodium glucose co-transporter 2 inhibitors.⁷ SBP = systolic blood pressure; SGLT2 = sodium glucose co-transporter 2.

What are SGLT2 inhibitors?

SGLT2 inhibitors are an established class of medications for the treatment of diabetes which act by preventing the absorption of glucose and sodium, mainly from the proximal renal tubule in the kidney. Glucose and sodium are, therefore, lost in urine. People do not become hyponatraemic (unless on diuretics as well) as most of the sodium is reabsorbed in the distal tubule. This effect results in decreasing the blood glucose level, weight loss, an osmotic diuresis and a drop in blood pressure (Fig 1).⁷ These drugs have been licensed and used widely in people with T2D and have shown significant cardiovascular and kidney benefits in different subsets of this group of patients.⁸

What are the benefits of using SGLT2 inhibitors?

Clinical trials using SGLT2 inhibitors have provided strong evidence in the trial population for reduced risk of major cardiovascular, renal and heart failure events (Tables 1 and 2: evidence differs for different agents within the class) in addition to reducing HbA1c by up to 10 mmol/mol (1.0%) depending upon the initial HbA1c. These medications are associated with a low incidence of hypoglycaemia, weight loss of up to 3 kg of body weight and a reduction in systolic blood pressure of approximately 3–5 mmHg. It is important to select the right patient for SGLT2 inhibitors in order to achieve health benefits (Box 1) without precipitating complications like DKA (Table 3).

What to do when initiating SGLT2 inhibitors: information for the patient

Treatment with SGLT2 inhibitors should be initiated only after ensuring adequate understanding of the person in the following aspects.

- > Discuss individualised benefits of taking SGLT2 Inhibitors.
- > Common side effects (Table 4).
- > Uncommon side effects (Table 4).
- > Foot care (Table 4).
- > Drink plenty of fluids to avoid dehydration unless you have been told to restrict fluids by your healthcare professionals due to heart or kidney problems or some other reason.

How to reduce the risk? Educate the patient about sick day guidance and DKA

When a person with diabetes is not well and is unable to eat and drink as normal, some simple rules can prevent further deterioration or DKA.¹⁸

- > If ill with diarrhoea, vomiting or fever and unusual drowsiness, stop SGLT2 inhibitors and don't restart until feeling better and eating/drinking fluids normally.
- > When people with diabetes who take insulin are not able to eat, it may be possible for them to consume half a glass of milk or fruit juice or yogurt or soup (not clear soup) in place of meals and follow individualised advice from their healthcare professionals about what dose of insulin to take.
- > Drink plenty of water / sugar-free fluid to avoid dehydration for up to 24 hours.
- > Seek medical advice if particularly unwell with infection or illness.

Table 1. Major sodium glucose co-transporter 2 inhibitor trials: summary of outcomes

Trial drug	Cardiovascular outcome trials in type 2 diabetes			Renal outcome trials		Heart failure outcome trials		
	CANVAS canagliflozin	DECLARE TIMI-58 dapagliflozin	EMPA-REG OUTCOME empagliflozin	VERTIS-CV ertugliflozin	CREDESCENCE canagliflozin	DAPA-CKD dapagliflozin	DAPA-HF dapagliflozin	EMPEROR-REDUCED empagliflozin
n	10,142	17,160	7,020	8,246	4,401	4,304	4,744	3,730
Baseline participant characteristics	65% established CVD; 35% risk factors for CVD	40% established CVD; 60% risk factors for CVD	All established CVD	All established CVD	All T2D with established diabetic kidney disease	All chronic kidney disease with or without T2D	All HFREF II-IV with or without T2D	All HFREF II-IV with or without T2D
Major adverse CV event (MACE)	↓14% ⁹	↔	↓14% ¹²	↔	↓20% ⁹	n/a	n/a	n/a
CV death and hospitalisation for heart failure	↓22% ¹⁰	↓17% ¹¹	↓34% ¹³	↔	↓31% ⁹	↓29% ¹⁵	↓25% ¹⁶	↓25% ¹⁷
Major adverse renal events	↓47% ⁹	↓47% ¹¹	↓39% ¹²	↔	↓30% ⁹	↓39% ¹⁵	↔	↓50% ¹⁷
Hospitalisation for heart failure	↓33% ⁹	↓27% ¹¹	↓35% ¹²	↓30% ¹⁴	↓39% ⁹	n/a	↓30% ¹⁶	↓31% ¹⁷
CV death	↔	↔	↓38% ¹²	↔	↔	↔	↓28% ¹⁶	↔
All-cause mortality	↔	↔	↓32% ¹²	↔	↔	↓31% ¹⁵	↓17% ¹⁶	↔

Trials differed in their design and population (included), therefore direct comparison should not be made. CV = cardiovascular; CVD = cardiovascular disease; HFREF = heart failure with reduced ejection fraction; n/a = not applicable; T2D = type 2 diabetes. Box colours: blue = confirmed significant risk reduction in primary outcome; green = significant risk reduction as exploratory outcome; yellow = no significant/neutral effect; grey = outcome not reported.

Table 2. Summary of licensed indications and recommended doses of sodium glucose co-transporter 2 inhibitors in type diabetes

SGLT2 inhibitor	Licensed indication	Dose adjustment recommendations as per kidney functions			
		eGFR >60	eGFR 45–59	eGFR 30–44	eGFR <30
Canagliflozin	Adults with insufficiently controlled T2D	Initiate 100 mg, titrate to 300 mg if needed	Initiate / continue with 100 mg only	Initiate / continue with 100 mg only if albuminuria >30 mg/mmol at initiation	Continue established treatment with 100 mg but do not initiate; stop if dialysis/transplant
Dapagliflozin	Adults with insufficiently controlled T2D	Initiate 10 mg	Continue with 10 mg but do not initiate	Not recommended	Not recommended
Dapagliflozin	HFrEF with or without T2D	Initiate 10 mg	Initiate 10 mg	Initiate 10 mg	Limited experience
Empagliflozin	Adults with insufficiently controlled T2D	Initiate 10 mg, titrate to 25 mg if required	Continue with 10 mg only; do not initiate	Not recommended	Not recommended
Ertugliflozin	Glycaemic control only	Initiate 5 mg, titrate to 15 mg if needed	Continue with 5 mg or 15 mg; do not initiate	Not recommended	Not recommended

In appropriate high-risk patients, a decision to treat with an SGLT2 inhibitor to reduce risk of cardiovascular, kidney and/or heart failure events should be considered **independent** of HbA1c.

- > Canagliflozin and empagliflozin have label indication for reducing major adverse CV events.^{9,12}
- > Canagliflozin, dapagliflozin and empagliflozin have shown reduction in hospitalisation for heart failure and to reduce chronic kidney disease progression in CV trials^{9,11,12}
 - > canagliflozin and dapagliflozin have primary renal outcome data^{9,15}
 - > canagliflozin is now licenced for the treatment of diabetic kidney disease in T2D⁹
 - > dapagliflozin and empagliflozin have primary heart failure outcome data^{16,17}
 - > dapagliflozin is now licenced for the treatment of heart failure with reduced ejection fraction in people with or without T2D.¹¹ When used in people with GFR <45, the effect on glucose lowering is likely to be minimal or absent but the medication is still indicated for people with heart failure with reduced ejection fraction.

Further trial results in areas of chronic kidney disease and heart failure are coming which may impact licensed indications in future. Please refer to current SmPC for individual drug for latest information on licenced indications and dose adjustment recommendations.

CV = cardiovascular; eGFR = estimated glomerular filtration rate (mL/min/1.73 m²); HbA1c = glycated haemoglobin; HFrEF = heart failure with reduced ejection fraction; SGLT2 = sodium glucose co-transporter 2; SmPC = summary of product characteristics; T2D = type 2 diabetes. Box colours: green = initiate; yellow = can initiate in certain circumstances; orange = do not initiate but can continue established treatment; red = treatment not recommended.

Box 1. Who is likely to benefit most from sodium glucose co-transporter 2 inhibitor treatment?

It is important to select the right patient for SGLT2 inhibitor therapy and avoid in others who may be at high risk of DKA.¹⁸ The following patients are likely to benefit most.

- > Adults above 18 years with T2D and one or more of the following:
 - > established / high risk of cardiovascular disease^a
 - > chronic kidney disease with albuminuria^a
 - > history of heart failure^a
 - > inadequate glycaemic control with need to minimise hypoglycaemia
 - > inadequate glycaemic control with need to minimise weight gain / encourage weight loss.
- > Patients with a clear understanding of the risks associated with SGLT2 inhibitors and how to reduce those risks.

^aPlease refer to Table 1 for evidence of benefit for individual agents. DKA = diabetic ketoacidosis; SGLT2 = sodium glucose co-transporter 2.

- > DKA is an uncommon but serious side effect characterised by the build-up of acidic chemicals in the blood called ketones.²³
- > Ketones are produced due to insulin deficiency in the body which can be absolute or relative.
- > Illness, infections, starvation, carbohydrate deficient diet, excessive exercise, alcohol, surgery, illicit drugs, reduced insulin dose (if on insulin) and dehydration increase the risk of DKA.
- > Be aware that glucose levels can be normal because of the way SGLT2 inhibitors work. Thus, ketone levels can be high even with a normal glucose!
- > If you have nausea, vomiting, abdomen pain, stupor, fatigue and difficulty breathing, then you or people close to you should suspect DKA and seek immediate medical advice.
- > Urine ketone levels are not always reliable. Test your capillary ketone if you have a ketone meter or go to your local hospital for blood ketone testing.
- > If ketones are >1.5 mmol/L, further blood tests may be needed to confirm or exclude DKA.

Table 3. Who is likely to be at risk with sodium glucose co-transporter 2 inhibitors?**Use with caution in the following situations:**

- > Person adhering to a ketogenic diet
- > Body mass index under 25 kg/m² (under 23 kg/m² in South Asian patients)
- > Person considered at high risk of acute effects of hyperglycaemia (such as dehydration due to non-adherence to medication)
- > Person with very high level of HbA1c >86 mmol/mol (~10% in old HbA1c units)
- > People diagnosed with or at risk of frailty
- > Cognitive impairment as it may interfere with the adequate understanding to take action to prevent and identify DKA
- > On chronic oral steroids
- > Recent weight loss
- > Long duration of diabetes (generally over 10 years from diagnosis)

Avoid in the following situations:

- > Past history of diabetic ketoacidosis
- > Eating disorder
- > eGFR lower than allowed in the up-to-date licensing of the medication being considered
- > Person with excess alcohol consumption or IVDU
- > Unwell person (acute medical illness including COVID-19, surgery or planned medical procedure)
- > Any diagnosis or suspicion of diabetes due to other causes, including T1D,^a latent autoimmune diabetes (LADA), other genetic causes of diabetes, known pancreatic disease or injury, or people who rapidly progressed to needing insulin within 1 year of diagnosis
- > Pregnant, breast feeding, female in the child-bearing years and sexually active without contraception
- > Age <18 years
- > Suspected or possible T1D except under specialist supervision (dapagliflozin 5 mg only)^a
- > Inpatient with acute vascular event who is not stable

Seek advice from the local diabetes team if unsure about the benefits and risks. ^aOnly dapagliflozin 5 mg is licensed for use in T1D in certain circumstances and should be initiated and supervised by a specialist. Sotagliflozin (SGLT1+2 inhibitor) 200 mg is also approved by NICE for similar circumstances but not currently available in the UK. eGFR = estimated glomerular filtration rate; DKA = diabetic ketoacidosis; HbA1c = glycated haemoglobin; IVDU = intravenous drug users; NICE = National Institute for Health and Care Excellence; T1D = type 1 diabetes.

Table 4. Adverse reactions to sodium glucose co-transporter 2 inhibitors^{9,11,12,19–21}

Adverse reaction	Frequency	Notes
Genital mycotic infections	Common / very common	Both male and female. Provide genital hygiene advice. Most initial cases can be treated with topical antifungals and won't recur. Consider reviewing therapy if recurrent infections.
Increased urination	Common	Increased frequency and/or increased volume.
Urinary tract infections	Common	In recent large trials, any increase in risk was small and non-significant.
Volume depletion side effects (thirst, postural dizziness, hypotension and dehydration)	Common/uncommon (varies with agent)	Caution in frail/elderly. Consider measuring blood pressure in lying and standing position in those at risk of fall and those on diuretics
Diabetic ketoacidosis	Rare: <1/1,000 in SmPC (between 0 and 2 additional events per 1,000 person-years in RCTs); real life events may be higher	Inform and advise patients and healthcare professionals about how to prevent diagnose and treat DKA
Amputation	Uncommon: event rate <1/100 in SmPC (between 0 and 3 additional events per 1,000 person-years in RCTs); ^a real-life events may be lower	Encourage routine preventative foot care; regular foot checking Advise patients to report wounds, discoloration or tender/painful feet Consider stopping therapy if significant foot problems arise (such as infection or skin ulcers)

^aExcess amputations were only seen in one study; subsequent studies with the same SGLT2 inhibitor and others have not confirmed a significant increase; any risk is likely to be very low. Necrotising fasciitis (Fournier's gangrene): post-marketing reports have been reported (six yellow card reports in >500,000 patient-years. Recent large trials have not shown any increase in risk. Patients should be advised to seek urgent medical attention if they experience fever/malaise along with pain, tenderness or redness in the genital or perineal area.²² DKA = diabetic ketoacidosis; SmPC = summary of product characteristics. Frequency: very common = ≥1/10; common = ≥1/100 to <1/10; uncommon = ≥1/1,000 to <1/100; rare = ≥1/10,000 to < 1/1,000.

- As ketones may lead to worse surgical outcome, SGLT inhibitors should be stopped 48 hours before elective surgery. However, ketones should be tested for in the presence of symptoms suggestive of DKA even after interruption of SGLT2 inhibitors. In addition, ketones should be periodically checked (as required) if the admission is for emergency surgery. SGLT2 inhibitors can be restarted 24 hours after resuming normal oral intake.
- Useful information has been produced by national cardiology, renal and metabolic associations which can be downloaded and shared with people with diabetes.²⁴

What to do when initiating SGLT2 inhibitors: information for the prescriber

When SGLT2 inhibitors are started, the healthcare provider should document completion of the education session with the person with diabetes and offer some advice on who to contact if the person taking the SGLT2 inhibitor is not feeling well. Glucose lowering medications that may cause hypoglycaemia, such as insulin and sulphonylureas, should be reviewed and consideration should be given to reduce the dose when SGLT2 inhibitor is started, particularly if the individual's HbA1c is at target when the treatment is being initiated. If the insulin requirement reduces considerably, one should be cautious of a higher risk of developing DKA. The healthcare professional should review diuretic and anti-hypertensive therapy periodically if hypertension improves or if there is postural hypotension.

How to reduce the risk of DKA and manage it? Educate the health professionals

In patients with diabetes on SGLT2 inhibitors with symptoms suggestive of DKA, ketosis should be confirmed by measuring capillary or venous blood ketone. If the ketone levels are above 1.5 mmol/L, acidosis should be checked by measuring venous bicarbonate (<18 mmol/L) or venous pH (<7.38). Blood glucose level in this situation can be normal because SGLT2 inhibitors induce glucose excretion. If DKA is confirmed (ketones >3.0 mmol/L, bicarbonate <15 mmol/L and pH <7.30), then the severity will be assessed by local criteria and treated according to the Joint British Diabetes Society (JBDS) guidelines or a locally adapted protocol.²³ Intravenous glucose in addition to fixed rate insulin infusion may be required to avoid hypoglycaemia while treating euglycaemic DKA.

When to stop treatment with SGLT2 inhibitors?

It is useful to remember that SGLT2 inhibitors may have to be temporarily stopped in situations which can increase the risk of DKA. Healthcare professionals should be especially careful in the following situations. After an episode of DKA the medications should not be restarted in future.

- Suspend SGLT2 inhibitors in the following circumstances:
 - acute medical admission including COVID-19
 - admission for elective surgery or procedure requiring starvation
 - vomiting
 - dehydration.
- Restart only AFTER patient has been eating normally for AT LEAST 24 hours AND no longer acutely unwell.
- Alternative diabetes treatment may be required in the interim.

In summary, SGLT2 inhibitors are a major advance in the management of T2D with additional cardiovascular and renal benefits. These drugs are now being commonly used by primary care physicians, cardiologists and nephrologists and some understanding of their potential benefits and possible side effects is critical. ■
